M Rajendraprasad, B Vidyasagar, G Uma Devi and SR Koteswar Rao

Abstract

In vitro evaluation was conducted with twenty four isolates representing two different species Trichoderma harzianum and Trichoderma viride and twelve different Bacillus subtilis and Pseudomonas fluorescense. These potential biocontrol agents were tested for their efficacy against phytopathogenic fungi through dual culture technique. Therefore, these effective biocontrol agents can be used for greenhouse studies to confirm the feasibility of using in tomato damping off disease management. The combination of potential Trichoderma spp and Pseudomonas fluorescense bacterial biocontrol agents (T7 and T3 treatments) also proved effective in increasing germination and to reduce pre and post emergence damping off in the pots when inoculated with Pythium debaryanum. The lowest incidence (45.00 percent) of pre emergence damping off was recorded in T7 (seed treatment with Trichoderma harzianum - 7 + soil application with Pseudomonas fluorescense-3). Among the bio-control treatments the lowest (47.92 and 52.08) post emergence damping off incidence was recorded in T7 (seed treatment with Trichoderma harzianum -7 + soil application with Pseudomonas fluorescense-3) at 30 and 50 DAS. The combination Trichoderma spp and Pseudomonas fluorescense bacterial biocontrol agents (T6 and T7) treatment also proved effective in increasing the shoot and root weight and fresh and dry weight of tomato plants when inoculated with Pythium debaryanum.

Keywords: Pythium debaryanum, Trichoderma harzianum, Pseudomonas fluorescense, Tomato damping off.

1. Introduction

Tomato (Lycopersicon esculentum, Mill) is one of the important vegetable crop in India and world. It is considered as ‘Protective food’ because of its nutritive value and year round production throughout the country. Soil borne fungal pathogens such as Pythium spp., Rhizoctonia solani and Sclerotium rolfsii infects the tomato crop causing damping off disease and is becoming a potential threat to its cultivation. Pythium debaryanum, a member of class Oomycetes, is one of the important soil-borne plant pathogen and it causes great loss in agriculture production. This fungus like organism is an unspecialized parasite that has a wide host range. Young tissues and plants are infected and affected much more severely by this pathogen. It causes damping off disease in several plants including tomato; it affects the plant both in pre and post emergence stage in nursery beds. Even though this pathogen can be controlled by some fungicides, nowadays researchers are more interested on biological control agents and their antifungal metabolites due to the notification of resistance development in the pathogen. Biological control is an alternative approach to the chemical fungicides and it may be a safe, effective and ecofriendly method for plant disease management. Damping-off of tomato caused by Pythium debaryanum was reduced by the application of talc based formulation of Trichoderma viride and Pseudomonas fluorescense in nursery beds before sowing. Besides reducing the pre - and post-emergence damping off these antagonists’ increased the root length, shoot length and biomass production of tomato seedlings. These antagonists significantly reduced the population of P. debaryanum in soil. Damping-off is an important disease of tomato, causing significant losses in nurseries where young susceptible transplants are produced. A pot culture experiment was conducted in the green house to study the efficacy of effective fungal or bacterial bio-control agents against test pathogen.

2. Material and Methods

2.1 Mass Multiplication of Pathogen

The test pathogen Pythium debaryanum isolated form diseased plants and multiplied on sorghum grains. Sorghum grains were pre-soaked in 2 percent sucrose solution overnight,
drained and boiled in fresh water for 30 minutes and drained again. This was transferred into 1000 ml flasks @ 400 g and autoclaved for 15 lb psi for 20 minutes. The flasks were allowed to cool at room temperature and inoculated with 5 mm discs of 3 to 4 day old culture of *Pythium debaryanum* grown on PDA or carrot agar. Seven discs per flask were added and the flasks were incubated for three weeks at 28 ± 2 °C.

2.2 Sterilization of soil

Soil was sterilized with formaldehyde for 3 days, after which it was dried in a cool and shady place. The seeds were sown in sterilized soil (Jeyarajan et al., 1994). The seeds of tomato cv. Arka Vikas were treated with Thiram @ 3 g kg⁻¹ seed using gum (5 ml kg⁻¹) as sticker. The treated seeds were spread over a clean paper and dried in a cool and shady place. The seeds were sown immediately after drying. The tare based formulations of fungal and bacterial bioagents were applied to soil @ 20 g kg⁻¹ soil (Jeyarajan et al., 1994). The seeds of tomato cv. Arka Vikas were treated with Thiram @ 3 g kg⁻¹ seed using gum (5 ml/kg) as sticker and the treated seeds were used for sowing. The various treatments and their combinations from T₁ to T₈ with three replications were imposed on tomato seedling to record.

Plants were grown for a period of 50 days i.e. till the period of harvest and the data on pre-emergence and post emergence damping off (%) at 10, 30, 50 DAS was recorded. Seeds of tomato cv. Arka Vikas used in experiments and seed treatment with tare based potential fungal and bacterial antagonist *T. harzianum* -7 and *P. fluorescence* -3 were used and treated @ 10 g kg⁻¹ of the seed using gum (5 ml kg⁻¹) as sticker. The treated seeds were spread over a clean paper and dried in a cool and shady place. The seeds were sown immediately after drying. The tare based formulations of fungal and bacterial bioagents were applied to soil @ 20 g kg⁻¹ soil (Jeyarajan et al., 1994). The seeds of tomato cv. Arka Vikas were treated with Thiram @ 3 g kg⁻¹ seed using gum (5 ml/kg) as sticker and the treated seeds were used for sowing. The various Treatments and their combinations from T₁ to T₈ with three replications were imposed on tomato seedling to record.

Number of seeds germinated

\[
\text{Number of seeds germinated = Total number of seeds sown} 
\]

i) Percent germination (PG) = \[ \frac{\text{Number of seeds germinated}}{\text{Total number of seeds sown}} \times 100 \]

ii) Percent disease incidence (PDI) = \[ \frac{\text{Number of wilted plants}}{\text{Total number of plants}} \times 100 \]

The growth parameters like shoot length, root length, total seedling length, fresh and dry weights.

3. Results and Discussion:

3.1 Bio-control of damping off disease on tomato cv. Arka Vikas

The effect of potential bio-control agents alone or in combination was studied for their ability to enhance seed germination and to reduce the damping off incidence caused by *Pythium debaryanum* under artificially inoculated conditions in glass house on tomato cv. Arka Vikas. The effect of different treatments on percent seed germination, pre and post emergence damping off was studied and the results are presented here under.

3.1a Percent germination

The results of experiments presented in Table (1), Plate 1 and Figure-1 showed that the percent germination of tomato seeds in all the treatments (39.58 to 57.08) was significantly higher as against 26.25 percent in the inoculated control. Among the individuals treatments, T₁ (seed treatment with thiram) recorded highest (57.08) percent germination followed by T₃ (seed treatment with *Trichoderma harzianum* -7 + soil application with *Pseudomonas fluorescence* -3), T₁ (seed treatment with *Trichoderma fluorescens* -3 + soil application with *Trichoderma harzianum* -7) with 55.08 and 51.25 percent respectively, which were statistically on par. However, treatment T₂ (soil application with *Trichoderma harzianum* -7) recorded least (39.58 percent) germination of tomato seeds.

3.1b Pre and post emergence damping off incidence

It is obvious from Table-2 and Plate. 1 that, all the treatments significantly reduced the disease incidence over control. The pre-emergence damping off incidence ranged between 42.92 to 60.42 percent in various treatments. The minimum percent post emergence damping off incidence was recorded in the treatment T₁ (seed treatment with thiram) when compared to control (73.75 percent).

Among the bio-control treatments, the lowest damping off incidence (45.00) was recorded in T₅ (seed treatment with *Trichoderma harzianum* -7 + soil application with *Pseudomonas fluorescens* -3) followed by T₆ (seed treatment with *Pseudomonas fluorescens* -3 + soil application with *Trichoderma harzianum* -7) and T₂ (soil application with *Trichoderma harzianum* -7) at 30 DAS in various treatments. The lowest (47.08) post emergence of damping off incidence was recorded in T₁ treatment (seed treatment with thiram) when compared to inoculated control (84.58). Among the bio-control treatments the lowest (47.92) incidence was recorded in T₈ (seed treatment with *Trichoderma harzianum* -7 + soil application with *Pseudomonas fluorescens* -3) followed by T₈ (seed treatment with *Trichoderma fluorescens* -3 + soil application with *Trichoderma harzianum* -7), T₃ (seed treatment with *Pseudomonas fluorescens* -3 + soil application with *Trichoderma harzianum* -7) and T₄ (seed treatment with *Trichoderma fluorescens* -3 + soil application with *Trichoderma harzianum* -7) at 30 DAS in various treatments.

3.2 Effect of bio-control agents on pre emergence damping off incidence

The treatment T₁ (seed treatment with thiram) recorded significantly lower damping off incidence (4.08) as against 16.58 recorded in T₈ (seed treatment with *Pseudomonas fluorescens* -3 + soil application with *Trichoderma harzianum* -7). The lowest damping off incidence was recorded in T₈ (seed treatment with *Pseudomonas fluorescens* -3 + soil application with *Trichoderma harzianum* -7) recorded least (35.58 percent) damping off incidence.
treatment with *Pseudomonas fluorescence*-3), T4 (seed treatment with *Trichoderma harzianum*-7), T5 (soil application with *Pseudomonas fluorescence*-3) and T2 (soil application with *Trichoderma harzianum*-7) with 53.33, 55.42, 58.33, 61.25 and 68.83 percent respectively. The post emergence damping off after 50 DAS sowing was ranged from 52.08 to 70.0 when compared to control (87.10). The least (52.08) was recorded in the treatment T3 (seed treatment with *Trichoderma harzianum*-7 + soil application with *Pseudomonas fluorescence*-3) followed by T7 (seed treatment with thiram), T6 (seed treatment with *Pseudomonas fluorescence*-3 + soil application with *Trichoderma harzianum*-7), T3 (seed treatment with *Pseudomonas fluorescence*-3), T1 (seed treatment with *Trichoderma harzianum*-7), T4 (soil application with *Pseudomonas fluorescence*-3) and T2 (soil application with *Trichoderma harzianum*-7) with 54.17, 57.50, 60.0, 61.67, 66.25 and 70.0 percent respectively. However the treatments T3 and T5, T3 and T6, T3 and T1 were statistically on par.

In the present study, all the treatments enhanced seed germination and suppressed pre and post emergence damping off incidence. Among all the treatments, T5 (seed treatment with *Trichoderma harzianum*-7 + soil application with *Pseudomonas fluorescence*-3) recorded maximum percent germination with minimum percent of damping off incidence. The seed treatment with thiram (T7) supported maximum germination and reduced the incidence of damping off. The effectiveness of Thiram and other chemicals in controlling tomato damping off was reported by Krishnamoorthy and Baskeran (1990). Among the bio-control treatments, T3 (seed treatment with *Trichoderma harzianum*-7 + soil application with *Pseudomonas fluorescence*-3) was found be best in increasing the germination of the seeds and reducing the damping off incidence compared to individual treatments. The effectiveness of *Trichoderma* and several bacterial biocontrol agents in reduction of tomato damping off incidence, was reported by Wolfhechel and Funck jensen (1992), Mehata *et al.* (1995) [8], Dinakaran and Ramakrishnan (1996) [2], Karthikeyan *et al.* (1999) [5].

The reduction or suppression of damping of incidence by bio-control agents maybe due to production of hydrolytic enzymes secreted by bio-control agents which help in entry of antagonists to pathogens through penetration with direct lysis and degradation of cell walls as reported by Chet and Baker (1981) [1]. Similarly Elad *et al.* (1987) [3] also reported the ability of *Trichoderma* isolates to control *P. aphanidermatum, S. rolfsii* in soil was achieved through hydrolytic enzyme production. It is evident from the results that the application of antagonists in combination showed synergistic effect on *P. aphanidermatum*.

3.2 Effect of biocontrol agents on growth parameters of tomato cv. Arka vikas

The influence of biocontrol agents alone and in combination on the growth parameters such as shoot length, root length, total length and fresh and dry weight were studied in pots under greenhouse conditions and the results are presented here under Table-(3) and Figure-(2).

3.2a Shoot length

There was significant increase in shoot length in various treatments compared to pathogen check. Maximum shoot length of 35.0 cm was recorded in T2 (seed treatment with thiram) followed by T6 (seed treatment with *Pseudomonas fluorescence*-3). The length of 35.0 cm was recorded in T2, T3 and T4, while T1 and T5 recorded minimum shoot length of 20.0 cm. The treatments T1 and T3 were on par with each other with regard to shoot length.
3.2b Root length
It is obvious from the Table -3 and Figure-2, that treatment T7 (seed treatment with thiram) recorded significantly highest root length 7.20 cm followed by T6 (seed treatment with Pseudomonas fluorescense-3 + Soil application with Trichoderma harzianum -7), T5 (Seed treatment with Trichoderma harzianum -7 + Soil application with Pseudomonas fluorescense-3) with 6.96, 6.43 cm respectively. The treatments T6 and T5 were on par with each other. Among all the treatments, T4 (soil application with Pseudomonas fluorescense-3) recorded minimum root length of 2.92 cm. The other treatments T3, T1 and T2 recorded root length of 3.76, 3.50 and 3.23 cm respectively.

3.2c Total length
The total length also increased significantly over control. The treatment T7 (seed treatment with thiram) recorded 4.06 g followed by T6 (seed treatment with Pseudomonas fluorescense-3 + Soil application with Trichoderma harzianum -7), T5 (seed treatment with Trichoderma harzianum -7 + soil application with Pseudomonas fluorescense-3), T3 (Seed treatment with Pseudomonas fluorescense-3), T1 (seed treatment with Trichoderma harzianum -7) and T2 (soil application with Trichoderma harzianum -7), recorded 39.96, 35.43, 28.76, 27.50 and 24.43 cm respectively when compared to control (16.20 cm). While the treatment T4 (soil application of Pseudomonas fluorescense-3) recorded the minimum total length of 22.92 cm.

3.2d Fresh weight
The fresh weight of tomato seedlings increased in all the treatments compared to control (Fig.4.13). The treatment T7 (seed treatment with thiram) recorded 4.06 g followed by T6 (seed treatment with Pseudomonas fluorescense-3 + soil application with Trichoderma harzianum -7), T5 (seed treatment with Trichoderma harzianum -7 + soil application with Pseudomonas fluorescense-3), T3 (Seed treatment with Pseudomonas fluorescense-3), T1 (seed treatment with Trichoderma harzianum -7) and T2 (soil application with Trichoderma harzianum -7), recorded 3.80, 3.70, 3.53, 2.60 and 2.52 g respectively, when compared to control (1.66 g). While the treatment T4 (soil application of Pseudomonas fluorescense-3) recorded minimum fresh weight of 2.40 g.

3.2e Dry weight
The dry weight of tomato seedlings increased significantly in all the treatments compared to control. The treatments T7 (seed treatment with thiram) recorded 0.43g followed by T6 (seed treatment with Pseudomonas fluorescense-3 + Soil application with Trichoderma harzianum -7), T5 (seed treatment with Trichoderma harzianum -7 + Soil application with Pseudomonas fluorescense-3), T3 (Seed treatment with Pseudomonas fluorescense-3), T1 (Seed treatment with Trichoderma harzianum -7) and T2 (Soil application with Trichoderma harzianum -7), recorded 0.40, 0.39, 0.35, 0.26 and 0.23 g respectively when compared to control (0.17). While the treatment T4 (soil application of Pseudomonas fluorescense-3) recorded minimum dry weight of 0.21 g.

In the present study, among the bio-control treatments, T6 (seed treatment with Pseudomonas fluorescense-3 + Soil application with Trichoderma harzianum -7) treatment was found to be effective to enhance the shoot length, root length and fresh and dry weight over other treatments. The results are in agreement with the results of Manoranjitham et al. (1999) who reported that combined seed treatment with t alc based formulations T. viride + P. fluorescense recorded maximum shoot length (4.45 cm), root length (13.50 cm), dry matter production (6.77 mg) against P. aphanidermatum.

Combined seed treatment with T. viride and B. subtilis resulted in increased fresh and dry weight of shoots, roots and nodules of broad bean apart from controlling infection by F. solani (Yehia et al. 1982) [10]. While the results of treatments T6 (combined seed treatment of ThM + P. fluorescense) is in agreement with Jensen et al. (2002) [1] who reported that B. subtilis in combination with T. harzianum when given as a seed treatment, resulted in increased biomass of dry apart from decreasing the severity of F. solani f.sp phaseoli infection.

### 4. Conclusion

A pot culture experiment was conducted to study the effect of potential fungal and bacterial bio-control agents alone or in combination for their ability to enhance seed germination and to reduce disease incidence of damping off caused by *Pythium debaryanum* under artificially inoculated conditions in glass house on tomato cv. Arka Vikas. Seed and soil application of *Trichoderma harzianum*-7 and *Pseudomonas fluorescence*-3 for *Pythium debaryanum* and combination of both the bioagents was tested against the pathogens. Fungicidal seed treatment with Thiram for *Pythium* was also included as one of the treatment in the present experiment. The percent germination of tomato seeds in all the treatments was significantly higher when compared with the inoculated
control in the presence of *Pythium debaryanum*. The treatment, T7, i.e., seed treatment with thiram for *Pythium* (57.08) recorded highest percent germination in tomato. However, seed treatment and soil application of both fungal and bacterial bioagents were also found equally good in enhancing the germination of tomato when inoculated with the three pathogens *Pythium debaryanum*. Seed treatment with *Trichoderma harzianum* -7 + soil application with *Pseudomonas fluorescence*-3 (T3) followed by seed treatment with *Pseudomonas fluorescence*-3 + soil application with *Trichoderma harzianum* -7 (T6) recorded 55.08 and 51.25 percent germination respectively when inoculated with *Pythium debaryanum*. While T2 (soil application with *Trichoderma harzianum* -7) recorded least (39.58 percent) germination of tomato seeds.

It is observed that seed treatment with *Trichoderma* and soil application of bacterial isolate was effective for increasing the germination percentage when inoculated with *Pythium debaryanum*. The pre emergence damping off caused by *Pythium debaryanum* (42.92) was minimum when treated with thiram. Among the bio-control treatments, seed treatment with *Trichoderma harzianum* -7 and *Pseudomonas fluorescence*-3 recorded low pre emergence damping off caused by *Pythium debaryanum*.

The data on post emergence damping off was recorded at 30 and 50 DAS. Seed treatment with thiram (T9) showed lowest incidence of (47.08, 52.08) followed by T7 (seed treatment with *Trichoderma harzianum* -7 + soil application with *Pseudomonas fluorescence*-3) (47.92 and 52.08) incidence *Pythium debaryanum* when compared to inoculated control (84.58, 70.00) at 30 and 50 DAS.

The influence of bio-control agents alone and in combination on the growth parameters such as shoot length, root length, total length, fresh and dry weight were also studied when inoculated with *Pythium debaryanum*.

Maximum shoot and root length was recorded in T7 (seed treatment with thiram) in *Pythium debaryanum* (35.0cm, 7.2cm) inoculated pots. The combination of fungal and bacterial treatment T6 (seed treatment with *Pseudomonas fluorescence*-3 + soil application with *Trichoderma harzianum* -7) recorded high shoot and root length of 33.0, 6.96 cm respectively in *Pythium* inoculated plants while T3 (seed treatment with *Trichoderma harzianum* -7 + soil application with *Pseudomonas fluorescence*-3) recorded 29.0 and 6.43 cm respectively.

The total length also increased significantly over control in the treatment T7 (seed treatment with thiram 23.46 cm 8.83 cm) recorded with 42.20 cm and the low (22.92) in T4 (soil application of *Pseudomonas fluorescense*-3). The combination of fungal and bacterial treatment T6 and T3 recorded 39.96, 35.43 cm respectively.

The fresh and dry weight of tomato seedlings also increased in the treatment T7 (seed treatment with thiram) with 4.06 g and 0.43 g respectively. Among the biocontrol treatments T6 (seed treatment with *Pseudomonas fluorescense*-3 + soil application with *Trichoderma harzianum* -7) recorded fresh and dry weight of 3.80 and 0.40 g while T5 recorded 3.70 and 0.39 g respectively.
