Abstract

An experiment was conducted on experimental farm Department of Agronomy, College of Agriculture, Vasantrao Naik Marathwada Krishi Vidyapeeth, Parbhani, during kharif season 2017, entitled “Studies on relationship between crop growth and yield and physical environment within the crop canopy of Sesame (Sesamum indicum L.) under different weather conditions”. An experiment was conducted in randomized block design with six replications. Treatment under study were four sowing dates in kharif season i.e. D1 (23th MW), D2 (25th MW), D3 (27th MW) and D4 (29th MW), and one variety AKT-64. The results found that all the biometric observations (plant height, No. of leaves, No. of branches and dry matter, days to 50% flowering and days to capsule formation, yield contributing characters such as total number of capsules plant\(^{-1}\), seed yield (kg/ha\(^{-1}\)), straw yield (kg/ha\(^{-1}\)) and biological yield (kg/ha\(^{-1}\)), were significantly highest yield in sown in D2 (25th MW) followed by D1 (23th MW). Sowing at D2 (25th MW) found superior over the rest of treatments with production of highest grain yield (440.8 kg/ha\(^{-1}\)) followed by sowing in first sowing date D1 (23th MW) (386.3 kg/ha\(^{-1}\)), third sowing date D3 (27th MW) (317.8 kg/ha\(^{-1}\)) and lowest grain yield was observed in fourth sowing D4 (29th MW) (237.2 kg/ha\(^{-1}\)).

Keywords: Sesame, sowing dates, weather parameters and sesame yield

Introduction

Sesame (Sesamum indicum L.) belongs to the family Pedaliaceae and is one of the most ancient oilseed crop used in cooking. The crop has origins in East Africa and India. It is also known as Benniseed, Ginigelly, Simsim, Ajonjoli, sesame and til. It was major oilseed crop in the ancient world due to its easiner of extraction, great stability and resistance to drought. Sesame crop cultivated though out the year. Crop also cultivated either as a pure stand or as a mixed crop with aus rice, jute, groundnut, millets and sugarcane (Bedigian et al., 2003) \([1]\). Sesame is basically considered a crop of warm region of tropics and subtropics. It requires fairly hot condition during growth to produce maximum yield. A temperature of 25-27 °C encourage rapid germination, initial growth and flower formation. It can be cultivated in kharif and rabi season. It is capable of withstanding a higher degree of water stress than many other cultivated plants. sesame requires the optimum temperature during its life cycle 25-35 °C. If the temperature is more than 45 °C with hot winds the oil content reduces. If the temperature goes beyond 45 °C or less than 15 °C there is a severe reduction in yield. The seedling stage, however, is extremely susceptible to moisture shortage. It will produced an excellent crop with a rainfall of 500-650 mm Ranganatha (2013) \([10]\) Sesame yield is highly variable depending upon the growing environment, cultural practices and cultivars (Brigham, 1985) \([4]\). Since the yielding ability of sesame crop is determined by many yield components, all of which are substantially influenced by environmental conditions and agronomic packages.

Material and Method

The field experiment was conducted in on experimental farm Department of Agronomy, College of Agriculture, Vasantrao Naik Marathwada Krishi Vidyapeeth, Parbhani, during kharif season 2017. The topography of experimental site was fairly uniform and leveled. The treatment consisting of four sowing dates, i.e 23th MW, 25th MW, 27th MW, 29th MW with one sesame variety - AKT-64 and was sown in Randomize Block design and four replication.
After seed bed preparation, sowing was done by drilling. Sesame varieties were sown at 45 cm row to row and 15 cm plant to plant spacing. The seeds was put in soil approximately @ 2-3 cm depth. To maintain optimum plant population thinning and gap filling was carried out 15 and 10 days after sowing by keeping only one healthy seedling hill¹. The soil analyzed in experimental field selected for experiment is uniform with typical medium soil having medium fertility and fairly good drainage. fertilizer was applied through nitrogen dose @ 50 kg ha⁻¹ urea and single super phosphate @ 25 kg ha⁻¹ was applied through at sowing time. The total rainfall during crop growth period i.e. June 2017 to October, 2017 was 994.1 mm received in 43 rainy days. Observations were recorded on Meteorological parameter, plant height (cm), branches plant, dry matter accumulation plant, number of capsule/ plant, seed yield (kg/ha⁻¹), straw yield (kg/ha⁻¹) and biological yield (kg/ha⁻¹).

Results and discussion

Growth studies

The biometric observations of sesame were recorded on various growth characters viz., plant height, number of branches per plant, dry matter accumulation plant, days to 50% flowering, days to capsule formation and days to Maturity.

Plant height (cm)

Data in Table (1) revealed that the mean plant height was significantly influenced by different sowing dates. The kharif sesame sown during (25th MW) recorded significantly more plant height at 90 days after sowing (111.10 cm) over the rest of sowing dates and it was at par with (23rd MW) sowing date. Lowest plant height was recorded in 29th MW (99.03 cm) during all growth stages of crop. Sesame sown at 25th MW available more photoperiod as for reproductive stage as a result plant attained maximum plant height and also received good rainfall. During 29th MW rainfall at reproductive stage there was stress which limited the plant height. These results are similar by Gade (2013)[6].

Mean number of branches per plant

The data on mean number of branches per plant as influenced periodically by various treatments are presented in Table 1. It would revealed that the number of branches per plant Sowing of sesame at 25th MW produced significantly maximum number of branches (3.87) as other sowing dates at all growth stages while, it was at par with sowing at 23rd MW and followed by 27th MW and 29th MW respectively. Sowing of sesame at 25th MW received prolonged photoperiod and good rainfall during vegetative as well as reproductive stage.

As a result of more assimilates was utilized by plant in producing more branches. These results are similar by Ali et al. (2005)⁴ and Abdel Rahman et al. (2007)⁷.

Dry matter accumulation plant

The data on mean total dry matter accumulation plant as influenced periodically by various treatments are presented in Table 1. Sowing of sesame at 25th MW produced significantly maximum total dry matter accumulation plant¹ 37.62 (g) than other sowing dates at all growth stages while, it was at par with sowing at 23rd MW. However, minimum total dry matter accumulation plant¹ was recorded in 29th MW. Similar results were reported by Gite (2014)⁷.

Days to 50% flowering, days to capsule formation & days to Maturity

Data in Table (1) revealed that the sesame crop sown during 29th MW recorded significantly minimum days to 50% flowering (43 days), Days to capsule formation (48 days) & days to maturity (85 days) and maximum for 25th MW (46 days), Days to capsule formation (51.7 days) and days to maturity (90 days) respectively. The more BSS (hrs) was recorded in 29th MW than other sowing dates, because this meteorological parameter is very important to sesame crop for early flowering and maturity.

Post-harvest studies

Mean Number of capsules per plant

The data pertaining to mean number of capsules plant¹ as influenced by different treatments is show in Table (2). sesame crop sown in 25th MW recorded significantly higher mean number of capsules plant¹ (22.60) and followed by 23rd MW (20.9), 27th MW (19.2) and 29th MW (17.8) respectively. Due to favorable atmospheric conditions at former treatment, the number of capsules was higher as compared to other treatment. Similar result was found Tripathy et al (2016)¹⁰.

Yield (kg/ha⁻¹)

The data pertaining to seed yield and straw yield of sesame at harvest as influenced by sowing dates are presented in Table (2). It was significantly influenced by different sowing dates. Sesame sown 25th MW recorded maximum seed and straw yield (440.8 kg ha⁻¹) and (1268.6 kg ha⁻¹) respectively followed sowing dates in order of sequence were 23rd, 27th and 29th MW respectively. This might be the effect of optimum temperature, good rainfall and BSS (hrs) during crop growth period under former sowing date. The lowest seed yield was observed at 29th MW because attack of phyllophy disease. Similar results were reported by Choudhary et al (2015)⁴.

Conclusion

Based on the above findings, it may be concluded that the highest yield was recorded for end june sowing by sesame D2 (25th MW) produced significantly highest all growth characters and grain yield (440.8 kg/ha) as compare to rest of sowing dates.
