## Response of soybean (*Gycine max* L.) to exogenous application of gibberellic acid under rainfed conditions

MD Giri, CP Jaybhaye, YV Ingle and DG Kanwade

**Abstract**

A field experiment was carried out at Agriculture Research Station (Dr. PDKV), Buldana during 2016 on a vertisol soil, to study the response of soybean (*Gycine max* L.) to exogenous application of gibberellic acid under rainfed conditions. In soybean, 10 treatments comprising gibberellic acid-management practices (application of 15, 30, 45 ppm GA<sub>3</sub> at flowering, pod development stages and control) were tested on vertisol. Results indicated that two applications of 45 ppm GA<sub>3</sub> at flowering and pod development stages recorded significantly higher plant height, number of branches /plant, number of pods/ plant, seed index and grain yield (21% more than control), higher oil yield, rain water use efficiency and higher gross and net monetary returns.

**Keywords:** Soybean, foliar application, GA<sub>3</sub>, rain water use efficiency (RUE), oil content

**Introduction**

India has the fifth largest vegetable oil economy in the world. After cereals, oilseeds are the second largest agricultural commodity, accounting for the 14 per cent of the gross cropped area in the country. However, the country is meeting its edible oil demand by importing almost 50 per cent of its requirement. The per capita consumption of the vegetable oil is increasing very rapidly due to increase in population and improved economic status of the population. The demand has increased to about 12.6 kg/year compared to 4 kg/year in 1961, and the projected demand for the year 2020 is 16.38 kg/year. To meet this demand, the country will require nearly 21.8 million tons of edible oil. In this scenario, soybean could play a pivotal role. Due to the advances in knowledge of lipid biochemistry and the possibilities of enhancing quality and yield of edible oil in soybean, this has the potential of becoming a major oil producing crop globally (Agrawal *et al.*, 2013) [2]. Despite having made rapid stride for both coverage and total production, soybean still suffers on productivity front. There are a number of constraints, pertaining to climate, edaphic, production, and technology aspects that hinder higher productivity.

Plant growth regulators are organic compounds which, in small amounts, somehow modify a given physiological plant process. Gibberellins (GAs) play an essential role in many aspects of plant growth and development, such as seed germination, stem elongation and flower development (Yamaguchi & Kamiya, 2000) [14]. Maske *et al.* (1998) [5, 8] reported that application of GA<sub>3</sub> on soybean at early growth stages resulted in increased number of branches plant<sup>-1</sup>. Foliar application of GA<sub>3</sub> increased number of flowers, pods and test weight in soybean (Uddin, 2002) [12]. Application of GA<sub>3</sub> increased the seed yield of soybean crop (Deotale *et al.*, 1998, Maske *et al.*, 1998 and Uddin *et al.*, 2002) [5, 8, 12]. Gibberellin proved to be potential in increasing the yield components like the number of pods and seeds which resulted to the increase in yield in soybean crop (Leite *et al.*, 2003) [7]. With this background in view, the present investigation was planned with the following objectives: To assess the effect of GA<sub>3</sub> on growth and yield of soybean to assess the effect of GA<sub>3</sub> on economics of soybean production.

**Materials and Methods**

The present experiment was conducted at the Agriculture Research Station (Dr. PDKV), Buldana, Maharashtra, India during 2016. The soil of experimental plot was clayey and slightly alkaline (pH 7.9), with available nitrogen (245kg/ha), phosphorus (20.8 kg/ha)

and potassium (336 kg/ha) content. Geographically Buldana is situated between 20°32'07.27N 76°11'24.43E and its mean height above sea level is 654 m. It receives most of the rainfall from South-West monsoon, commencing from middle of June. The normal monsoon season precipitation approximates to about 720 mm receives in about 40 to 45 rainy days from the middle of June to September. The details of the crop season rainfall and its distribution during the experimentation period are given in Table 2 and 3 and also depicted in fig. 1. For studying the response of soybean (*Glycine max* L.) to exogenous application of gibberellic acid

under rainfed conditions, randomized block design was used. The details of the treatments and symbols used are given in Table 1. In all, there were ten treatments replicated three times. The experimental field was laid out in 30 unit plots, each plot measuring 10.80 m<sup>2</sup> (3.6m x 3.0m). There were eight rows of soybean crop in each plot and sixty plants in each row. One row of crop from both sides of length and also both sides of breadth were left as guard rows. The net plot consisted of six rows with fifty eight plants per row (2.70m x 2.90m).

Seeds of soybean variety JS- 335 were sown @ 30 kg/ ha (444444 plants/ ha) with the spacing of 45cm between rows and 05cm between plants on 7<sup>th</sup> July 2016. A fertilizer dose of 30 kg N, 75 kg P<sub>2</sub>O<sub>5</sub> and 30 kg K<sub>2</sub>O/ ha through urea, single super phosphate and muriate of potash was applied at the time of sowing (basal application) to all the plots. Foliar application of gibberellic acid was done as per the treatments. For the foliar application of gibberellic acid a stock solution of 1000ppm was prepared by using 1.1g gibberellic acid technical (90%) along with promix (solvent) dissolved in distilled water and made the volume to 1000ml using volumetric flask and from this stock solution required amount of the gibberellic acid as per the treatments was utilized for foliar application (Table 1). Timely recommended plant-protection measures for soybean crop were followed to save the crop from pests and diseases. The soybean crop was harvested manually. Different growth and yield components were recorded periodically. The data on various parameters recorded from experimental plots were statistically analyzed as suggested by Panse and Sukhatme (1995) <sup>[9]</sup> by using 'F' test at P=0.05.

## Results and Discussion

**Table 4:** Effect of different treatments on growth and yield parameters of soybean

### Grain and straw yield

Application of GA<sub>3</sub> significantly influenced the soybean grain yield (Table 5). Two applications of 45 ppm GA<sub>3</sub> at flowering and at pod development stages (T<sub>10</sub>) recorded significantly higher grain yield (2733.06 kg/ ha). It has also recorded 21% more soybean grain yield than that of control plot (2260.52 kg/ ha). The grain yield of soybean increased due to cumulative effect of yield attributing characters and enhanced photosynthetic efficiency and greater diversion of assimilates towards reproductive organs. Results are in agreement with the work of Agawane and Parhe (2015) <sup>[1]</sup> and Upadhyay and Ranjan (2015) <sup>[13]</sup>.

### Growth and yield parameters

Exogenous application of GA<sub>3</sub> significantly influenced the soybean plant height, branches /plant, pods/ plant, seed index and grain yield/ plant (Table 4). Two applications of 45 ppm GA<sub>3</sub> at flowering and at pod development stages (T<sub>10</sub>) recorded significantly higher plant height, number of branches /plant, number of pods/ plant, seed index and grain yield/ plant. Superiority in growth parameters of soybean is due to foliar application of different concentrations of GA<sub>3</sub> over control possibly due to the physiological effects of gibberellins on growth parameters of plants like cell elongation and cell division, increase in photosynthetic activity and better food accumulation. The increase in plant height may be due to the effect of GA<sub>3</sub> on cell division and cell enlargement and also GA<sub>3</sub> stimulated the growth and expansion of cells through increasing the wall plasticity of the cells (Reza *et al.*, 2015) <sup>[10]</sup>. The foliar application of GA<sub>3</sub> at flower initiation and pod formation stage might have reduced flower drop and caused efficient translocation of photosynthates from source to sink. This might have significantly increased the number pods/ plant, grain mass and yield/ plant. Similar results were observed by Akter *et al.*, (2007) <sup>[3]</sup> and Ganapathy *et al.*, (2008) <sup>[6]</sup>.

### Harvest Index

Application of GA<sub>3</sub> significantly influenced the soybean harvest index (Table 5). Two applications of 45 ppm GA<sub>3</sub> at flowering and at pod development stages (T<sub>10</sub>) recorded significantly higher harvest index (44.14%) and it was at par with the two applications of 15 ppm GA<sub>3</sub> (T<sub>8</sub>), 30 ppm GA<sub>3</sub> (T<sub>9</sub>) and single application of 45 ppm GA<sub>3</sub> at pod development stage (T<sub>7</sub>). The higher harvest index indicated that, GA<sub>3</sub> application accelerated assimilate supply to sink, which is in agreement with the results of Akter *et al.* (2007) <sup>[3]</sup>.

**Table 5:** Effect of different treatments on grain and straw yield, oil content, oil yield and rainfall use efficiency of soybean

| Treatments      | Grain yield/ ha (kg) | Straw yield/ ha (kg) | Harvest Index (%) | Oil content (%) | Oil yield (kg/ ha) | Rain water use efficiency (kg/mm/ha) |

### Oil content and oil yield

The effect of exogenous application of GA<sub>3</sub> on oil content in soybean grain (%) was found non-significant (Table 5). However, two applications of 30 and 45 ppm GA<sub>3</sub> at flowering and pod development stages recorded the highest oil content in soybean grain, whereas no application of GA<sub>3</sub> (control) recorded the lowest oil content in soybean grain. This shows that the GA<sub>3</sub> has not much influence on oil content. This finding is well supported by Sharma *et al.* (2017). Oil yield (kg/ ha) was significantly influenced by the application of GA<sub>3</sub> (Table 5). All the treatments recorded statistically similar oil yield (kg/ ha) except no application of GA<sub>3</sub> (control) and single application of GA<sub>3</sub> at flowering stage (T<sub>2</sub>). The highest oil yield (505.6 kg/ ha) was observed under the treatment two applications of 45 ppm GA<sub>3</sub> at flowering and at pod development stages (T<sub>10</sub>). The increase

in the oil yield is directly correlated with the grain yield of the soybean. The best treatment recorded the higher grain yield of soybean and resulted in higher oil yield.

### Rain Water Use Efficiency (RUE)

Rain water use efficiency (kg/ mm/ ha) was significantly influenced by the application of GA<sub>3</sub> (Table 5). Two applications of 45 ppm GA<sub>3</sub> at flowering and at pod development stages (T<sub>10</sub>) recorded higher rain water use efficiency (4.79 kg/ mm/ ha). The lowest rain water use efficiency was observed with no application of GA<sub>3</sub> (3.97 kg/ mm/ ha). The best treatment recorded 20.65% more rain water use efficiency than the control treatment. This clearly indicates that application of GA<sub>3</sub> resulted in enhancing the effective use of rainfall by the soybean crop and it is reflected in the increment in yield.

**Table 6:** Economics of soybean as influenced by different treatments

| Treatments      | Cost of Cultivation (x 10 <sup>3</sup> Rs/ ha) | Gross Monetary Returns (x 10 <sup>3</sup> Rs/ ha) | Net Monetary Returns (x 10 <sup>3</sup> Rs/ ha) | B:C ratio |
|-----------------|--|---|---|-----------|
| T <sub>1</sub>  | 24.07  | 67.81b  | 43.74b  | 2.81      |

Market rates of soybean grains @ Rs. 3000/- per quintal

### Economics

Economics of soybean production was significantly influenced by the GA<sub>3</sub> application (Table 6). Two applications of 45 ppm GA<sub>3</sub> at flowering and pod development stages (T<sub>10</sub>) recorded significantly higher gross and net returns (Rs. 81992/- and Rs. 56307/- gross and net returns, respectively), which were higher by Rs. 14716/- and Rs. 12567/- than that of no application of the GA<sub>3</sub> (Rs. 67816/- and Rs. 43740/- gross and net returns, respectively). The benefit: cost ratio was higher with the two applications of GA<sub>3</sub> at flowering and pod development stages (T<sub>9</sub>). Increased grain yield owing to application of GA<sub>3</sub> significantly

increased the gross and net monetary returns. The results confirm the findings of Aziz *et al.* (2012) [4].
