# Effect of integrated nutrient management on economic yield of cut flower of China aster (Callistephus chinensis L. Nees) 

Raj Kumar, Ashok Kumar and Ravi Pratap Singh

#### Abstract

The present investigation entitled "Effect of integrated nutrient management on economic yield of cut flower of China Aster (Callistephus chinensis L. Nees)" was carried out at Main Experiment Station, Department of Horticulture, Narendra Deva University of Agriculture \& Technology, Kumarganj, Faizabad, (U.P.) during the year 2015-16 to 2016-17. The experimental material i.e. China aster cv. Prince. The experiment was laid out in randomized block design with sixteen treatments comprising of PSB, Azotobacter and FYM alone or in combination with each other and variable doses of N, P and K in three replications. The experimental results have clearly showed that the application of recommended nitrogen, phosphorus and potassium can be saved with the application of vermicompost and dual inoculation of Azospirillum and PSB besides obtaining higher flower yield of china aster. Therefore, it may be concluded that the use of $\mathrm{T}_{15}-\mathrm{Azo}+\mathrm{PSB}+\mathrm{VC}+50 \%$ RDF helped in realizing, higher quality of flower yield ( $216.49 \mathrm{q} / \mathrm{ha}$ in 2015-16 and $220.91 \mathrm{q} / \mathrm{ha}$ in 2016-17) and above all, in the $\mathrm{C}: B$ ratio ( 1.41 in 2015-16 and 1.45 in 201617) above all, in the production of china aster (Callistephus chinensis L. Nees) cv. Prince in eastern Uttar Pradesh.

Keywords: Integrated nutrient, management, economic yield, China aster

## Introduction

China aster [Callistephus chinensis (L.) Nees.], belongs to family Asteraceae and is a native of China and Europe. The genus Callistephus derived its name from two greek words 'Kalistos' and 'Stephos' meaning 'most beautiful' and 'a crown', respectively. Cassini described the China aster as Callistephus hortensis. It was first named by Linnaeus as Aster chinensis, and Nees changed this name to Callistephus chinensis. China aster is a very popular annual flower crop and is mainly cultivated for production of cut flowers, loose flowers, as pot plant and for bedding plant purposes in landscape. It is gaining fast popularity in India because of its easy cultural practices, diversity of colours and varied uses. Evolution of aster flowers brought a new range of colours starting from white, rose, red, lavender, magenta and blue to their innumerable variations.
The plants of China aster are erect and attain a maximum height of $60-80 \mathrm{~cm}$ depending upon the genotypes. China aster is a half hardy annual, plants are erect, branches having hispid hair, leaves are arranged alternately on branches, broadly ovate or triangular ovate, deeply and irregularly toothed and the flowers are solitary. The aster blooms consist of two kinds of florets: ray florets and disc florets. The disc florets are short while the ray florets are usually long. The most suitable character for the classification of China aster is by the shape of ray florets. A comprehensive and updated account on the cultivation and breeding of China aster is provided in an ICAR bulletin.
Flower quality is primarily a varietal trait and is influenced by climatic conditions prevailing during growing period. Optimum temperature and requisite photoperiod go a long way in obtaining better blooms of good size and high quality.

## Materials and Methods

The present investigation entitled "Effect of integrated nutrient management on economic yield and cut flower of China Aster (Callistephus chinensis L. Nees) cv Prince was carried out at Main Experiment Station, Department of Horticulture, Narendra Deva University of Agriculture \& Technology, Kumarganj, Faizabad, (U.P.) during the year 2015-16 to 2016-17.

The experiment was laid out in randomized block design with sixteen treatments comprising of PSB, azotobacter, vermicompost, poultry manure and FYM alone or in combination with each other and variable doses of $\mathrm{N}, \mathrm{P}, \mathrm{K}$ in three replications.
The observations with respect to height of yield of cut flower and C : B ratio were recorded during both cropping years i.e. 2015-16 and 2016-17.

## Results and Discussion

## Number of cut flower per plant

The higher number of cut flower per plant (8.02) was counted in $\mathrm{T}_{15}$ (Azo $+\mathrm{PSB}+\mathrm{VC}+50 \% \mathrm{RDF}$ ) as compared to other treatment including $\mathrm{T}_{4}(\mathrm{FYM}+50 \% \mathrm{RDF})(4.15)$ treatment $\mathrm{T}_{13}$ (Azo $+\mathrm{PSB}+50 \% \mathrm{RD}$ ' N ' and $\mathrm{P}+100 \% \mathrm{RD}$ ' K ') and $\mathrm{T}_{16}$ (Azo $+\mathrm{PSB}+\mathrm{PM}+50 \% \mathrm{RDF}$ ) found at par.Similar pattern noted in 2016-17 with maximum number of cut flower per plant (8.27) observed in $\mathrm{T}_{15}$ (Azo $+\mathrm{PSB}+\mathrm{VC}+50 \%$ RDF) as compared to other treatment at least being in $\mathrm{T}_{4}$ (FYM + 50\% RDF) (4.27) (Table 1). Smita et al. (2006) and Manjusha et al. (2006).

## Number of cut flower per hectare

The maximum number of cut flower per hectare ( $8.99 \mathrm{q} / \mathrm{ha}$ ) was obtained $\mathrm{T}_{15}$ (Azo $+\mathrm{PSB}+\mathrm{VC}+50 \% \mathrm{RDF}$ ) which found significantly higher that other treatment including $\mathrm{T}_{4}$ (FYM $+50 \% \mathrm{RDF}$ ) ( $4.64 \mathrm{q} / \mathrm{ha}$ ) treatment $\mathrm{T}_{14}(\mathrm{Azo}+\mathrm{PSB}+$ $\mathrm{FYM}+50 \% \mathrm{RDF}$ ), $\mathrm{T}_{16}$ (Azo + PSB + PM + 50\% RDF) found at par. Similar pattern was followed in second year. Slightly more number of cut flower per hectare was recorded in this year with the maximum ( $9.18 \mathrm{q} / \mathrm{ha}$ ) being in $\mathrm{T}_{15}$ (Azo + PSB $+\mathrm{VC}+50 \% \mathrm{RDF}$ ) and the minimum ( $4.73 \mathrm{q} / \mathrm{ha}$ ) recorded in $\mathrm{T}_{4}$ (FYM $+50 \%$ RDF) (Table 1). Smita et al. (2006) and Manjusha et al. (2006).

## Flower yield per hectare

The maximum flower yield ( $216.49 \mathrm{q} / \mathrm{ha}$ ) flower yield was achieved with the application of $\mathrm{T}_{15}$ (Azo + PSB $+\mathrm{VC}+50 \%$ RDF) followed by $\mathrm{T}_{16}(\mathrm{Azo}+\mathrm{PSB}+\mathrm{PM}+50 \% \mathrm{RDF})$ and
$\mathrm{T}_{14}$ (Azo + PSB + FYM + 50\% RDF). The minimum flower yield per quintal was observed $\mathrm{T}_{3}$ (PSB $+75 \% \mathrm{RD}$ ' P ' + $100 \% \mathrm{RD}$ ' N ' and K ) (103.77). It is interesting to mention that combined application of organic manure (216.49) was found significantly superior over application of inorganic manure (169.02) (Table 1).
Data also indicated that more number of organic combination (Azo + PSB+ FYM + 50\% RDF) and other. Similar patter was followed in 2016-17 with the observation that slightly more flower yield was recorded. However the maximum yield ( $220.91 \mathrm{q} / \mathrm{ha}$ ) was obtained in $\mathrm{T}_{15}$ (Azo $+\mathrm{PSB}+\mathrm{VC}+50 \%$ RDF) and least being in $\mathrm{T}_{3}$ ( $\mathrm{PSB}+75 \% \mathrm{RD}$ ' P ' $+100 \% \mathrm{RD}$ ' N ' and K) ( $105.89 \mathrm{q} / \mathrm{ha}$ ). Arora and Saini (1976); Yasin and Pappiah (1990); Singh and Arora (1980); Syamal et al. (1990); Serawat et al. (2003) and Sharma et al. (2006).

## Economics

The maximum average cost of cultivation of Rs. 93685.00 for the cropping years 2015-16 and 2016-17 was computed under the treatment of Azo + PSB + PM + 50\% RDF ( $\mathrm{T}_{16}$ ), while the lowest cost of cultivation of Rs. 88085.00 was obtained with the FYM $+50 \%$ RDF and $\mathrm{VC}+50 \% \mathrm{RDF}\left(\mathrm{T}_{4}\right.$ and $\mathrm{T}_{5}$ ). The highest average gross return of Rs. 216490.00 during both cropping years i.e. 2015-16 and 2016-17 was achieved due to application of Azo $+\mathrm{PSB}+\mathrm{VC}+50 \% \mathrm{RDF}\left(\mathrm{T}_{15}\right)$ while the lowest average gross income of Rs. 120250.00 was obtained with the application of FYM $+50 \%$ RDF $\left(\mathrm{T}_{4}\right)$. The highest net income of Rs. 126855.00 for the two cropping years i.e. 2015-16 and 2016-17, was recorded with the treatment combination of Azo + PSB + VC + 50\% RDF ( $\mathrm{T}_{15}$ ) whereas the lowest average net income of Rs. 3,67,279.00 was recorded under treatment of Azo + PSB $+50 \%$ RD ' N ' and $\mathrm{P}+100 \% \mathrm{RD}$ ' K ' $\left(\mathrm{T}_{3}\right)$. The highest average cost: benefit ratio 1:2.06 during both cropping years i.e 2015-16 followed by $\mathrm{T}_{14}$ (1:1.62). The lowest cost: benefit ratio (1:0.97) were recorded with $\mathrm{T}_{2}$ (Azospirillum $+75 \% \mathrm{RDN}+100 \% \mathrm{RD}$ ' P ' and K) (Table 1). Renukaradya et al. (2011) and Idan et al. (2014).

## Summery and Conclusion

- Maximum number of flower per plant were counted in Azo + PSB + VC + 50\% RDF during 2015-16 and 201617.
- Observations made for number of flower per plant recorded the maximum values with the treatment combination of Azo + PSB + VC + 50\% RDF during both the years of investigation.
- The highest average weight of flower per plant was obtained with the treatment Azo + PSB + VC + 50\% RDF in both the years.
- The treatment combination of Azo + PSB + VC + 50\% RDF produced the maximum number of flower per hectare during 2015-16 and 2016-17 also.
- Plants nourished with Azo + PSB + VC + 50\% RDF yielded the maximum flowers during 2015-16 and also in successive years of experimentation.
- Due to the maximum harvest of loose and cut in $\mathrm{T}_{15}$ treatment condition comprised of Azo + PSB + VC + $50 \% \mathrm{RDF}$, the highest cost: benefit ratio of 1:2.74 was recorded.

From the above study, it could be concluded that the application of Azo $+\mathrm{PSB}+\mathrm{VC}+50 \%$ RDF responded as best treatment for almost all the parameters included under study. Keeping in view, overall performance of organic manures like Phosphate solubility Bacteria, Azotobacter, Farm Yard manure and inorganic fertilizers viz. Nitrogen, Phosphorus and Potassium. The application of Azo + PSB + $\mathrm{VC}+50 \% \mathrm{RDF}$ can be recommended for China aster cultivation in eastern Uttar Pradesh for better economic return.
