DOI: <https://doi.org/10.22271/chemi.2021.v9.i1aj.11611>

Abstract

The present investigation was carried out at the Experimental Farm, Division of Vegetable Science, SKUAST-K, Shalimar, India during *Kharif* season 2020. Fifty-seven treatments comprising of 45 F₁'s, 10 parents and 2 checks were evaluated for various yield and yield attributing traits in Augmented Bock Design (ABD). Analysis of variance revealed significant differences among the parents (accessions) as well as their crosses for all the traits under both environments, in the individual as well as in pooled data analysis. The maximum fruit yield hectare⁻¹ (q) was recorded in the accession EC-520074 (961.69) and cross EC-914092 x EC-914097 (1026.39) in E₁; accession EC-914097 (719.69) and cross EC-914092 x VRT-02 (971.62) in E₂ and accession WIR-3957 (611.93) and cross WIR-5032 x EC – 914092 (898.59) in pooled data analysis indicating that these should be considered for further improvement in future breeding programmes in terms of fruit yield hectare⁻¹.

Keywords: Variance, check, environment, genotype, cross

Introduction

Cherry tomato (*Solanum* spp., 2n=2x=24), one of the important botanical variety of the cultivated tomato (*Solanum lycopersicum* L.) is a member of nightshade family ‘Solanaceae’, consisting of 96 genera (Akhtar *et al.*, 2013)^[2] and over 3000 species (Melomey *et al.*, 2019; Sharma *et al.*, 2019)^[9, 13] distributed in three subfamilies, Solanoideae (to which *Solanum* belongs), Cestroideae, and Solanineae (Knapp *et al.*, 2004; Akhtar *et al.*, 2013)^[8, 2], all of which are diploid except two natural tetraploid populations of *S. chilense* (2n=4x=48) (Chetelat and Ji, 2007; Grandillo *et al.*, 2011)^[4, 6]. It is typically a day neutral plant, that often requires long growing periods to fetch more harvests and is one of the most promising crop under protected structures or shade net conditions (Vidyadhar *et al.*, 2014) and reasonably tolerant to heat and drought. Being a self-pollinated crop, a definite degree of cross-pollination (0.07-10.0%) also occurs in it when stigma protrudes outside the level of anther (exerted) (Accotto *et al.*, 2005). It is also known as salad tomato as its fruits are consumed more as a fruit rather than as a vegetable (Islam *et al.*, 2012).

Cherry tomato is native to the Andean region encompassing Ecuador and Peru of South America and thereafter it spread around the world following the Spanish colonization of the Americas (Grandillo *et al.*, 2011)^[6]. It was first found throughout tropical and subtropical America, later propagated in the tropics of Asia and Africa (Gharezi *et al.*, 2012; Venkadeswaran *et al.*, 2018)^[5, 14] and is widely distributed in California, Korea, Germany, Mexico and Florida (Anonymous, 2009a)^[3]. Though it became popular as a cash crop in various Asian countries, but it is still new in India as well as in Kashmir, as such its area, production and productivity has not been documented till date. But in Himachal Pradesh, protected cultivation of cherry tomatoes has been gaining importance from previous 5-6 years, on account of favourable growing conditions inside the polyhouse.

It is perennial in its native habitat but is often grown as an annual crop in temperate climate. The growth habit of the plant is usually indeterminate and may reach up to 3 meters in height. The flowers are perfect and hermaphrodite and contain 5 green sepals, 5 yellow petals, 5

stamens alternate with petal position, protective anthers (fused to form an anther cone) that surrounds the stigma and short style. Dehiscence of anthers occurs from base to top (longitudinal) and one or two days after opening of corolla (Rolf, 2009)^[12].

Materials and Methods

The present investigation was carried out at Vegetable Experimental Farm, Division of Vegetable Science, SKUAST-Kashmir, Shalimar, India during *Kharif* season, 2020 under two environments namely open environment (E_1) and protected environment (E_2). The altitude of the location is 1685 meters above mean sea level and situated at $34^{\circ}14'$ North latitude and $74^{\circ}86'$ East longitude. The climate is temperate characterized by mild summers and very cold winters. The mean minimum and maximum temperatures are recorded in the months of January and June respectively. The maximum rainfall is received during the months from March to April with an average around 1380.20 mm for the year 2019-2020.

Fifty-seven treatments comprising of 45 F_1 's, 10 parents and 2 checks were evaluated for various yield and yield attributing traits in Augmented Block Design. The seeds of all accessions and their crosses were first sown in nursery and then transplanted to the main field at a spacing of 60 x 60 cm between rows and plants respectively. Recommended package of practices were followed to raise a healthy crop. The observations were recorded on 16 quantitative traits *viz.*, plant height, number of primary branches plant⁻¹, days to first flowering, days to first fruit set, days to first fruit maturity, number of clusters plant⁻¹, number of flowers cluster⁻¹,

number of fruits cluster⁻¹, number of fruits plant⁻¹, number of locules fruit⁻¹, fruit length, fruit diameter, average fruit weight, pericarp thickness, fruit yield plant⁻¹ and fruit yield hectare⁻¹ by selecting five random plants and the average was worked out.

Results and Discussion

In this study, all the cherry tomato accessions (parental genotypes) and their crosses showed wide range of variability for most of the morphological and growth characters (Table-1.0 to 6.0) under both environments, in the individual as well as data pooled over environments. The estimates of mean values revealed that no accession as well as cross was superior for all the characters under study. However, different accessions as well as crosses were found to reveal superiority for different traits.

Based on the overall performance of various cherry tomato accessions (parental genotypes) and their crosses, the accession EC-520074 (961.69) and cross EC-914092 x EC-914097 (1026.39) in E_1 ; accession EC-914097 (719.69) and cross EC-914092 x VRT - 02 (971.62) in E_2 and accession WIR-3957 (611.93) and cross WIR - 5032 x EC - 914092 (898.59) in pooled data analysis were found to be best with respect to yield hectare⁻¹ (q) indicating that these should be considered for further improvement in future breeding programmes.

Similar findings with respect to mean performance has also been reported by Renuka *et al.* (2014), Chaudhari *et al.* (2018), Omprasad *et al.* (2018), Panchbhaiya *et al.* (2018), Venkadeswaran *et al.* (2018)^[14], Kannaujia, *et al.* (2019) and Tsagaye *et al.* (2020).

*, ** Significant at 5 and 1 per cent levels, respectively

Conclusion

From this study, it is concluded that all the cherry tomato accessions (parental genotypes) and their crosses can be effectively distinguished by its various morphological and growth characters. In future, further studies need to be carried over locations or years to facilitate further utilization in breeding programme.

Acknowledgment

I am indebted to Dr. Khursheed Hussain for his guidance, technical support, field assistance and provision of facilities during the whole experimental programme.
