# Study of axis symmetric shapes of sessile drops 

Rajeev Ranjan Deo Pandey, Sumit Kaur and Binay Prakash Akhouri

#### Abstract

By fitting the Laplacian equation of capillarity to the dimensions of sessile drops, axis symmetric drop shape analysis (ADSA) techniques are presented for the computations of any one (the contact angle, the interfacial tension, and the radius of curvature at the drop apex) if the values of two other are known With the change of area of pendant drops, the change in Gibb's energy and the change in work done are computed. Numerically generated drop profiles used to demonstrate the accuracy and applicability of the method.

Keywords: Surface tension, axis symmetric drop shape analysis (ADSA), sessile drops

## Introduction

Surface tension is the boundary tension at a liquid-gas interface. The boundary tension at a liquid-liquid contact is termed as interfacial tension. The determination of liquid-gas surface tension and liquid-liquid interfacial tension is essential in a number of scientific and industrial fields. The capillary rise method ${ }^{[1-4]}$, the do Noisy ring method ${ }^{[5-7]}$, the Wilhelmy plate method ${ }^{[8,9]}$, the height of a meniscus on a vertical plane method ${ }^{[10,27]}$, the spinning drop method ${ }^{[11, ~ 12]}$, the maximum bubble pressure method ${ }^{[13,14]}$, the drop weight method ${ }^{[15,16]}$, and the drop or bubble shape analysis method ${ }^{[1-16]}$ have all been developed to measure surface/interfacial tension. Among these methods, drop shape analysis method has a number of advantages. The measurement of interfacial tension using drop form methods is powerful, diverse, and adaptable. While studying liquid-fluid menisci, Neumann and colleagues established the axis symmetric drop shape analysis (ADSA) numerical technique ${ }^{[17-18]}$ for calculating surface and interfacial tensions from the shape of drops or bubbles.
Today, ADSA ${ }^{[17-18]}$ has been widely used in a variety of applications, including cellular biomechanics and oil recovery. Bash forth and Adams ${ }^{[20]}$ developed sessile drop profiles for different surface tensions and radii of curvature at the apex of the drop, which was the first study in the field of axis symmetric drops analysis. Maze and Burnet ${ }^{[21]}$ devised a more precise approach for determining interfacial tensions based on the shape of sessile drops.
Further development of DSA techniques ${ }^{[17-36]}$ are ADSA-P ${ }^{[17-18]}$, ADSA-NA (No apex) ${ }^{[17]}$, ADSA-CSD (constrained sessile drop) ${ }^{[17]}$, ADSA-D(diameter) ${ }^{[17]}$, ADSA-HD (height and diameter) ${ }^{[22]}$, ADSA -TD( two diameter) ${ }^{[30]}$, ADSA-CB (captive bubble) ${ }^{[17-20]}$, and ADSAEF (electric field) ${ }^{[17]}$. The ADSA-EFis applicable to pendant and sessile drops/bubbles. For studying accuracy of drop shape techniques the geometrical shape parameters and physical dependence of shape parameters are primarily investigated.
In order to analyse physical dependence of shape parameters, the limitations of four drop shapes categories are principally presented which are, volume-radius limited ${ }^{[18]}$, Volumeangled limited ${ }^{[18]}$, volume-radius-radius limited ${ }^{[18]}$ and the volume-radius-angle limited ${ }^{[18]}$. For measuring interfacial tension, however, the approaches indicated above are more powerful, diverse, and adaptable.
For determining interfacial tension, a variety of approaches have been presented. There is currently a large body of literature documenting the new approaches as well as enhancements to old methods. However, only a few are of outstanding importance. We will discuss among them the most fundamental method i.e., the method for computing the interfacial tension from the shapes of sessile drops.

(ii) A sessile drop

(iii) A pendant drop with a cylindrical tip

(iv) A sessile drop in a capillary tube

Fig 1: Gives apresentation of a pendant and a sessile drop.

Pendant drops results (i) when the liquid drop is hanging from a flat, horizontal surface, or (ii) from a vertical cylindrical tip. Sessile drops are shaped like an oblate spheroid. They are formed (iii) when a drop of liquid settles on a flat, horizontal plate, or (iv) The liquid surface in a capillary tube also has the sessile shape. Pendant drops correspond to a prolate spheroid. The balance between surface tension and extrinsic forces, such as gravity, determines the shape of the drop/bubble. Gravity deforms the drop, elongating a pendant drop or flattening a sessile drop, whilst surface tension tries to round it. When the surface tension effect is substantially greater than the gravitational influence, the shape of both pendent and sessile drops/bubbles tends to become spherical. Theoretically, each drop shape corresponds to a constant surface tension value. A little change in surface tension generates a large change in shape for well-defined geometries. A considerable change in surface tension, on the other hand, generates just a modest change in shape for approximately spherical drop/bubble geometries. The connection between drop shape and surface tension lies at the heart of drop shape methods. The Laplace equation of capillarity includes this information. The drop shapes as in Figure 2 can be generated using a Laplace equation.

## Theory

When a drop of liquid with interfacial tension $\gamma$ is placed on a non-wetting solid surface, the drop assumes a shape that is determined by the contact angle $\theta_{c}$ that the liquid makes at the three-phase contact line, in accordance with the YoungDupré equation (see) ${ }^{[19]}$. Under static conditions, the drop shape must also satisfy the Young-Laplace equation of capillarity ${ }^{[37-38]}$, which describes the mechanical equilibrium conditions for two homogeneous fluids separated by an interface:
$\gamma\left(\frac{1}{R_{1}}+\frac{1}{R_{2}}\right)=\Delta P$

Where $R_{1}$ and $R_{2}$ are the two principal radii of curvature, $\gamma$ is the liquid-fluid interfacial tension, and $\Delta P$ is the pressure difference across the interface. In the absence of external forces other than gravity, the pressure difference is a linear function of the elevation:

$$
\begin{equation*}
\Delta P=\Delta P_{0}+(\Delta \rho) g z \tag{2}
\end{equation*}
$$

Where $\Delta P_{0}$ is the pressure difference at a reference plane, $\Delta \rho$ is the density difference between the two bulk phase, ${ }^{g}$ is the gravitational acceleration, and $z$ is the vertical height of the given point on the drop surface, measured from the reference level. The integration of the Laplace equation (1) is straightforward only for a cylindrical meniscii, i.e., menisci for which one of the principal radii of curvatures is zero. For a general irregular meniscus, numerical integration would be very difficult. For the specific case of axis-symmetric drops, e.g. sessile drops and pendant drop drops, numerical procedures have been devised ${ }^{[17-18]}$. Fortunately obtaining axial symmetry is not difficult for most sessile drop and pendant drop systems. For the axial symmetry of the
interface, the curvature at the apex is constant in all directions and the two radii of curvature are equal, i.e,

$$
\begin{equation*}
\frac{1}{R_{0}}=\frac{1}{R_{1}}=\frac{1}{R_{2}}=b \tag{3}
\end{equation*}
$$

At $s=0$, where $R_{0}$ and $b$ are the radius of curvature and the curvature at the $\operatorname{origin}(x=0$ and $z=0$ as shown in Fig.2) respectively. Then, from equation (1), the pressure difference at the origin can be expressed as

$$
\begin{equation*}
\Delta P_{0}=2 b \gamma \tag{4}
\end{equation*}
$$

Using equation (1), (2) and(3) we have the following form of Laplace equation:
$\gamma\left(\frac{1}{R_{1}}+\frac{1}{R_{2}}\right)=2 b \gamma+(\Delta \rho) g z$

Fig 2: Axis symmetric co-ordinate system
In this work, the shape of an axis-symmetric sessile drop is computed for given $\gamma, b=1 / R_{0}$, and contact angle $\theta_{c}$. The liquid is taken to be water and the surrounding fluid is air. For computational purposes it is convenient to work with arc length $s$ along the curve and the turning angle ${ }^{\phi}$, which is defined in terms of the local slope by $d z / d x=\tan \phi$. Introducing $\phi$ and the arc length $s$ (i.e., $d s=\sqrt{d x^{2}+d y^{2}}$ ) as new variables along the interface allows the Young-Laplace equation to be expressed as $d \phi / d s=2 b+c z-\sin \phi / x$ with $d x / d s=\cos \phi, d y / d s=\sin \phi$, and $d A / d s=2 \pi x$ and $d V / d s=\pi x^{2} \sin \phi$; where $V$ is the volume and $A$ the
surface area of the drop. Thus for a given $\gamma_{\text {and }} \theta_{c}$, specifying the reference curvature $b$ is equivalent to specifying the volume or surface area of the drop. $V$ (or $A$ ) decreases monotonically with increasing $b$. The capillary constant $c$ has positive values for sessile drops and negative values for pendant drop and is expressed as $c=(\Delta \rho) g / \gamma$. Here, $\Delta \rho=997.38 \mathrm{Kg} / \mathrm{m}^{3}$ and $g=9.8 \mathrm{~m} / \mathrm{s}^{2}$.

## Result and discussion

In numerically generated Figures $3(a)-3(g)$, we find that the curved surfaces changes, i.e., either moves outwards or inwards depending mainly on the values of the three parameters viz the contact angle $\theta_{c}$, the interfacial tension $\gamma$, and the radius of curvature $R_{0}$ at the drop apex. The parameterizations of the different quantities are as follows: $0<s<4, \quad 0<\theta_{c}<180^{\circ}, \quad 0<\gamma<72,-0.8<1 / R_{0}<0$ and $0.6<x<6$ and $0<y<-0.37$. For numerical evaluation of the drops the initial conditions used were set as: $\phi(0)=0, z(0)=0, x(0)=0, V(0)=0$ and $A(0)=0$.

Any plane's interaction with the curved surface generates a two-dimensional curvature containing one of the two independent radii of the curved surface ( $R_{1}$ and $R_{2}$ ). If the curved surface becomes a little larger and moves by an amount of $d z$, the new position of the surface will be formed. Therefore, there will be changes in surface dimensions $x$
(abscissa), ${ }^{y}$ (ordinate) and $z$ (normal coordinate to paper plain) to $x+d x, y+d y \quad$ and $z+d z$ amounts. Consequently, the changes in area, Gibbs free energy, and work will be:

$$
\begin{equation*}
\Delta A=(x+d x)(y+d y)-x y=x d y+y d x+d x d y \approx x d y+y d x \tag{6}
\end{equation*}
$$

$d G=\gamma(x d y+y d x)$
$W=\Delta P d V=\Delta P x y d z=\gamma(x d y+y d x)$

In table 1, it can easily be observed that the contact radius increases when the contact angle values increase from $30^{\circ}$ to $90^{\circ}$ and decreases when the contact angle value decreases from $90^{\circ}$ to $180^{\circ}$ for $1 / R_{0}=-5.05\left(\mathrm{~m}^{-1}\right), \gamma=50(\mathrm{~N} / \mathrm{m})$. In table2-4, it can also be observed that the same is true for every set of $1 / R_{0}\left(m^{-1}\right), \gamma(N / m)$ and $\theta_{c}$ (in degree). We can also calculate the change in Gibb's energy by using equation (6) and (7). In table 1, the change in area at two contact angles $30^{\circ}$ and $90^{\circ}$ is $(18.7733-3.1490) \times 10^{-6} \approx 15.624 \times 10^{-6} \mathrm{~m}^{2}$
Similarly, the change in area at two contact angles $90^{\circ}$ and $180^{0}$ is $(33.4525-18.7733) \times 10^{-6} \approx 14.699 \times 10^{-6} \mathrm{~m}^{2}$. Hence, the change in Gibbs energy for the two cases of contact angles is $-78.90 \times 10^{-6} \mathrm{Nm}$ and $-74.23 \times 10^{-6} \mathrm{Nm}$. Bash forth and Adams ${ }^{[20]}$ derived the theoretical form of sessile or pendant drop and calculated tables of drop contours. The interfacial tension of a sessile or a pendant drop was determined by matching the experimentally measured drop profile to a theoretical drop contour. However, the visual comparison of drop profiles was time-consuming, tedious and subjective.

## Conclusion

The surface energy of the solid sample may be calculated using two parameters: surface energy and especially the contact angle of the liquid droplet. It has also been discovered that the sessile drop analysis approach is useful for measuring contact angles. The change in Gibb's energy is determined using volume and area calculations. The significance of these computations can be seen from the concept of interfacial tension. By definition the interfacial tension is the increase in Gibb's free energy per increase of the surface area at constant $T, P$ and $N_{i}$.
